

Secure Vibe Coding Onboarding Process

1. Prerequisites:
 - a. Establish accounts on the following sites (b-f). I suggest you use a gmail account to simplify login.
 - b. Log into dashboard.clerk.com (using the same email address). Leave tab open.
 - c. Log into dashboard.convex.dev. Leave tab open.
 - d. Log into vercel.com. Leave tab open.
 - e. Log into github.com. Leave tab open.
 - f. Log into doppler.com. Leave tab open.
 - g. Install doppler cli: <https://docs.doppler.com/docs/install-cli>
 - h. Cursor, VS Code, Windsurf, or Antigravity Integrated Development Environment (IDE)
 - i. Git installed: <https://git-scm.com/install>
 - j. Nodejs (version 18+): <https://nodejs.org/en/download>
 - k. Claude Code installed: <https://code.claude.com/docs/en/quickstart>
2. Clone the Secure Vibe Coding OS to your machine, place it in a folder called “code”, and place all of your projects there, to keep things organized. In below command, you will see [application name], replace that with a short name for app, such as Health Test, Blue App, etc.
 - a. If you are not aware of how to clone a project into an IDE, follow these directions: <https://www.youtube.com/watch?v=34IbF6Ab4tU>
 - b. Otherwise, here is the command to clone the repo (run from command line):
git clone <https://github.com/harperaa/secure-vibe-coding-OS.git> [application name]
 - c. Either change directory (cd) into that new folder and launch your IDE or follow the directions in video and open the folder from within the IDE.
3. Inside the IDE, open a new terminal, CTR + Shift + ` (backtick), or as shown in the video.
4. Within that terminal, type “claude.”
5. Inside claude terminal, hit shift-tab until auto-mode shows, select yes. Only avail on Opus 4.7.
6. Inside claude terminal, type “/install.”
7. Follow directions, providing your application name and email address (option 3 on email tab).
8. Watch the claude code terminal and respond with “Yes” when asked to proceed, it may ask several times, depending on how your system is configured.
9. After the install completes, it will tell you what to do, open two more terminals and type: “npm run convex:doppler” into one and “npm run dev:doppler” into other terminal.
10. In the second terminal window, you will see a URL, such as <http://localhost:3000> hover over it to see instructions to click it an open or simply open a new browser tab and go to that URL.
11. Now, you can iterate the boiler plate application and have claude change the homepage and backend pages as you see fit. Test logging into the application, using the email you provided.
12. If you have an existing application, run “/port-old-site [path to that code],” to port it smartly.
13. When you are satisfied, within claude code terminal, type “/deploy-to-dev” to deploy the application to Github (private repo) and Vercel. It is already on Clerk and Convex.
14. To establish and keep a clean practice of github hygiene, follow the directions in the PDF provided in docs folder: docs/git_cicd_workflow_guide.pdf
15. When ready for real clients and data, then type “/deploy-to-prod,” and follow directions there.
16. If you have already have OS, but need to update it, use “/pull-repo-safe” to not step on files.
